# Chapter 5 Network Layer: The Control Plane

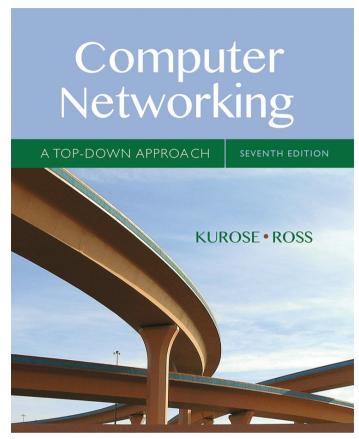

#### A note on the use of these Powerpoint slides:

We're making these slides freely available to all (faculty, students, readers). They're in PowerPoint form so you see the animations; and can add, modify, and delete slides (including this one) and slide content to suit your needs. They obviously represent a *lot* of work on our part. In return for use, we only ask the following:

- If you use these slides (e.g., in a class) that you mention their source (after all, we'd like people to use our book!)
- If you post any slides on a www site, that you note that they are adapted from (or perhaps identical to) our slides, and note our copyright of this material.

Thanks and enjoy! JFK/KWR

#### Computer Networking: A Top Down Approach

7<sup>th</sup> edition
Jim Kurose, Keith Ross
Pearson/Addison Wesley
April 2016

## Chapter 5: network layer control plane

chapter goals: understand principles behind network control plane

- traditional \_\_\_\_\_ algorithms
- Protocol
- network management

and their instantiation, implementation in the Internet:

 OSPF, BGP, OpenFlow, ODL and ONOS controllers, ICMP, SNMP

# Chapter 5: outline

- 5.1 introduction
- 5.2 routing protocols
- link state
- distance vector
- 5.3 intra-AS routing in the Internet: OSPF
- 5.4 routing among the ISPs: BGP

- 5.6 ICMP: The Internet Control Message Protocol
- 5.7 Network management and SNMP

# Network-layer functions

#### Recall: two network-layer functions:

: move packets	•
from router's input to	<u> </u>
appropriate router output	-

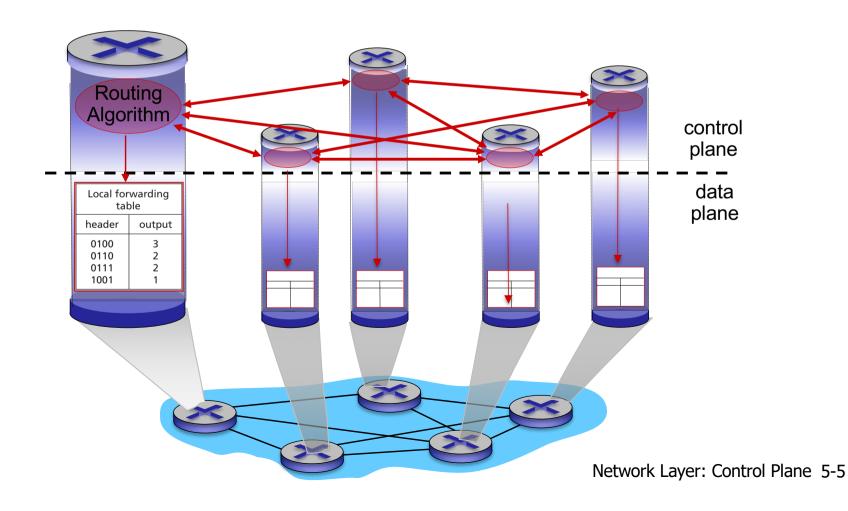

: determine route	_	
taken by packets from source	P	lane
to destination		

#### Two approaches to structuring network control plane:

- per-router control (traditional)
- logically centralized control (software defined networking)

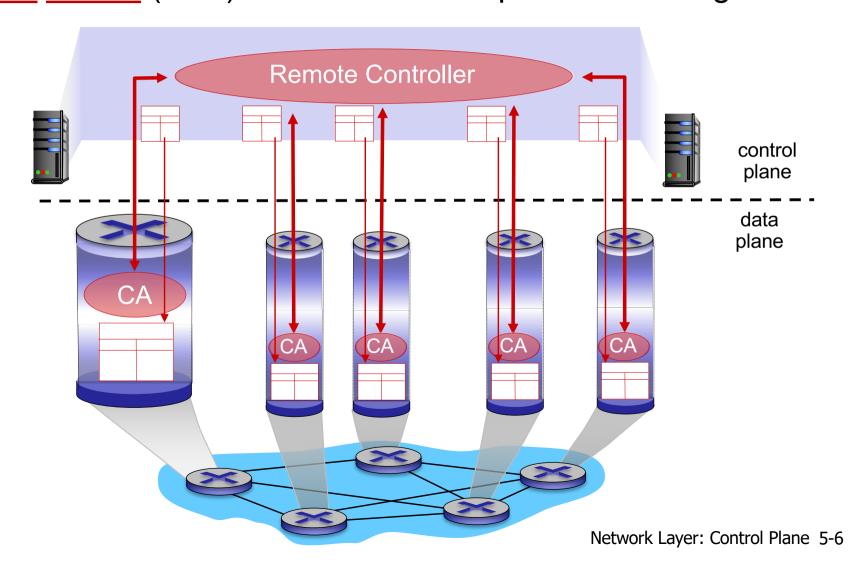

#### Per-router control plane

routing algorithm components in \_\_\_\_\_ and \_\_\_\_ router \_\_\_\_ with each other in control plane to compute forwarding tables

### Logically centralized control plane

A \_\_\_\_\_ (typically remote) controller interacts with \_\_\_\_ (CAs) in routers to compute forwarding tables

# Chapter 5: outline

- 5.1 introduction
- 5.2 routing protocols
- link state
- distance vector
- 5.3 intra-AS routing in the Internet: OSPF
- 5.4 routing among the ISPs: BGP

- 5.6 ICMP: The Internet Control Message Protocol
- 5.7 Network management and SNMP

### Routing protocols

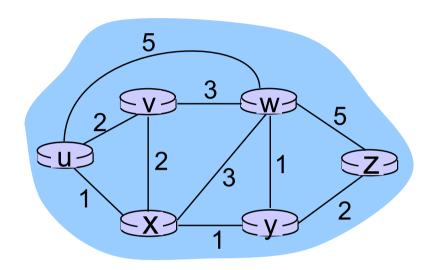

Routing protocol goal: determine "\_\_\_\_"
(equivalently, routes), from sending hosts to receiving host, through network of routers

path: \_\_\_\_ of \_\_\_ packets will \_\_\_\_ in going from given \_\_\_\_ source host to given final \_\_\_\_ host

"good": least "\_\_\_ ", "\_\_ ", "\_\_\_ "

routing: a "top-10" networking challenge!

### Graph abstraction of the network

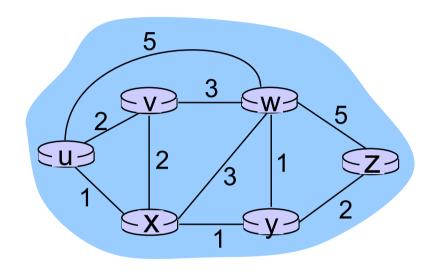

graph: G = (N,E)

 $N = set of routers = \{ u, v, w, x, y, z \}$ 

 $E = \text{set of links} = \{ (u,v), (u,x), (v,x), (v,w), (x,w), (x,y), (w,y), (w,z), (y,z) \}$ 

aside: graph abstraction is useful in other network contexts, e.g., P2P, where N is set of peers and E is set of TCP connections

# Graph abstraction: costs

$$c(x,x') = cost of link (x,x')$$
  
e.g.,  $c(w,z) = 5$ 

cost could always be 1, or inversely related to bandwidth, or inversely related to congestion

cost of path 
$$(x_1, x_2, x_3, ..., x_p) = c(x_1, x_2) + c(x_2, x_3) + ... + c(x_{p-1}, x_p)$$

key question: what is the least-cost path between u and z? routing algorithm: algorithm that finds that least cost path

### Routing algorithm classification

global or decentralized information?
bal:
all routers have
, link info
"" algorithms
centralized:
router knows
neighbors, link costs
to neighbors
process of
computation, of
with neighbors
" algorithms

#### Q: static or dynamic?

#### static:

routes change slowly over time

#### dynamic:

- routes change more quickly
  - periodic update
  - in response to link cost changes

# Chapter 5: outline

- 5.1 introduction
- 5.2 routing protocols
- link state
- distance vector
- 5.3 intra-AS routing in the Internet: OSPF
- 5.4 routing among the ISPs: BGP

- 5.6 ICMP: The Internet Control Message Protocol
- 5.7 Network management and SNMP

### A link-state routing algorithm

#### 's algorithm

- net topology, link costs known to all nodes
  - accomplished via "link state
  - all nodes have same info
- computes least cost paths from one node ('source") to all other nodes
  - gives forwarding table for that node
- iterative: after k iterations, know least cost path to k dest.'s

#### notation:

- C(X,y): link from node x to y; = ∞ if not direct neighbors
- D(V): current value of cost of path from source to . v
- P(V): \_\_\_\_ node along path from source to v
- N': set of whose least cost path known

# Dijsktra's algorithm

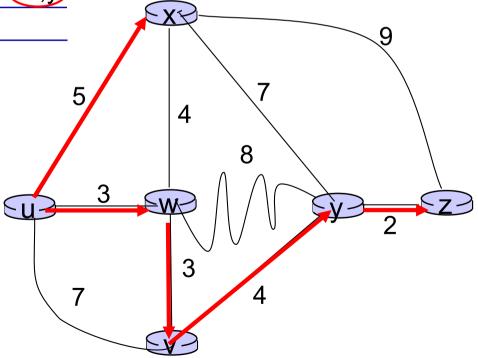

```
Initialization:
   N' = \{u\}
   for all nodes v
    if v adjacent to u
       then D(v) = c(u,v)
    else D(v) = \infty
   Loop
    find w not in N' such that D(w) is a minimum
   add w to N'
   update D(v) for all v adjacent to w and not in N':
      D(v) = \min(D(v), D(w) + c(w,v))
13 /* new cost to v is either old cost to v or known
14
     shortest path cost to w plus cost from w to v */
15 until all nodes in N'
```

# Dijkstra's algorithm: example

		$D(\mathbf{v})$	D(w)	D(x)	D(y)	D(z)
Step	o N'	p(v)	p(w)	p(x)	p(y)	p(z)
0	u	7,u	(3,u)	5,u	∞	∞
1	uw	6,w		5,u	) 11,w	∞
2	uwx	6,w			11,W	14,X
3	uwxv				10,V	14,x
4	uwxvy					(12,y)
5	uwxvyz		-	_	_	

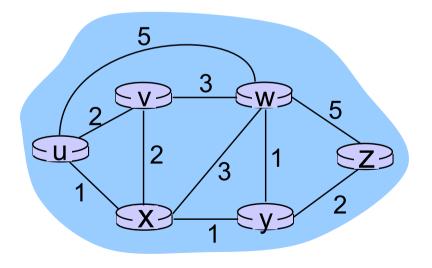

#### notes:

- construct shortest path tree by tracing predecessor nodes
- ties can exist (can be broken arbitrarily)

# Dijkstra's algorithm: another example

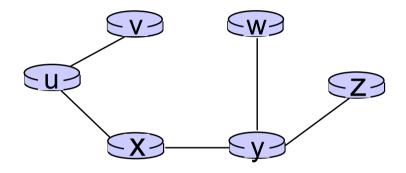

Ste	эр	N'	D(v),p(v)	D(w),p(w)	D(x),p(x)	D(y),p(y)	D(z),p(z)
_	0	u	2,u	5,u	1,u	∞	∞
	1	ux <b>←</b>	2,u	4,x		2,x	∞
	2	uxy <mark>←</mark>	2,u	3,y			4,y
	3	uxyv		3,y			4,y
	4	uxyvw 🗲					4,y
	5	uxyvwz <b>←</b>					

<sup>\*</sup> Check out the online interactive exercises for more examples: http://gaia.cs.umass.edu/kurose\_ross/interactive/

# Dijkstra's algorithm: example (2)

resulting shortest-path tree from u:

resulting forwarding table in u:

destination	link	
V	(u,v)	
X	(u,x)	
У	(u,x)	
W	(u,x)	
Z	(u,x)	

Network Layer: Control Plane 5-17

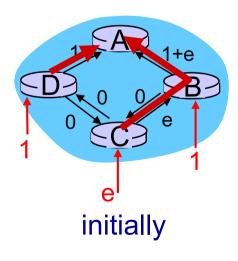

# Dijkstra's algorithm, discussion

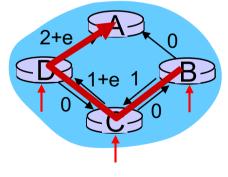

#### algorithm complexity: n nodes

- each iteration: need to check all nodes, w, not in N
- n(n+1)/2 comparisons:  $O(n^2)$
- more efficient implementations possible: O(nlogn)

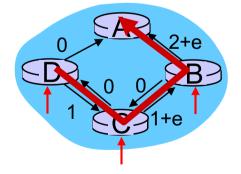

#### oscillations possible:

e.g., support link cost equals amount of carried traffic:

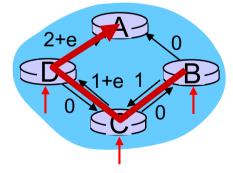

given these costs, find new routing.... resulting in new costs

given these costs, find new routing....

given these costs, find new routing.... resulting in new costs resulting in new costs

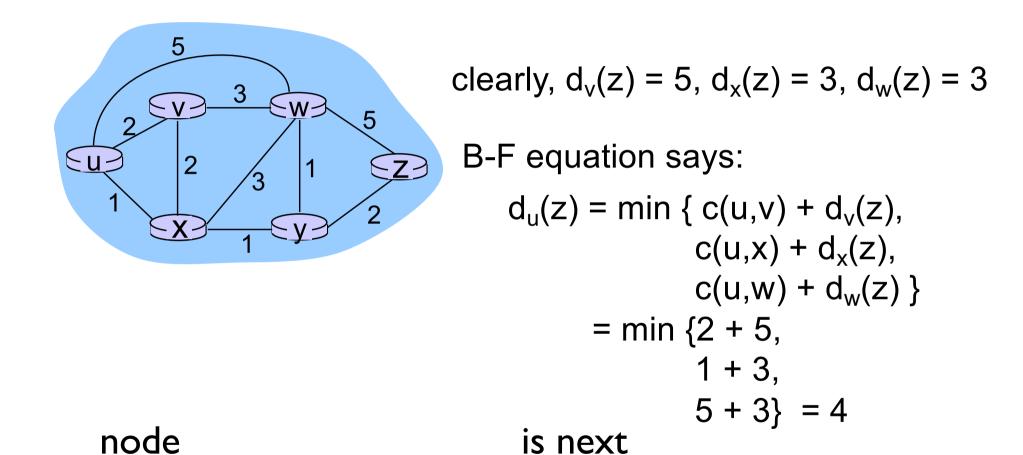

# Chapter 5: outline

- 5.1 introduction
- 5.2 routing protocols
- link state
- distance vector
- 5.3 intra-AS routing in the Internet: OSPF
- 5.4 routing among the ISPs: BGP

- 5.6 ICMP: The Internet Control Message Protocol
- 5.7 Network management and SNMP

equation (dynamic programming) let  $d_x(y) := cost of ____ path from ___ to _$ then  $d_{x}(y) = \min \{c(x,v) + d_{v}(y)\}$ cost from v to \_\_\_\_\_ y cost to neighbor v min taken over v of x

# Bellman-Ford example

path, used in

hop in

table

- $D_x(y)$  = estimate of least cost from x to y
  - x maintains distance vector  $\mathbf{D}_{x} = [\mathbf{D}_{x}(y): y \in \mathbb{N}]$
- node x:
  - knows cost to each neighbor v: c(x,v)
  - maintains its neighbors' distance vectors. For each neighbor v, x maintains

$$\mathbf{D}_{\mathsf{v}} = [\mathsf{D}_{\mathsf{v}}(\mathsf{y}): \mathsf{y} \in \mathsf{N}]$$

#### key idea:

- from \_\_\_\_\_\_, each node sends its \_\_\_\_\_distance vector \_\_\_\_\_\_ to neighbors
- when x receives new DV estimate from neighbor,
   it \_\_\_\_\_ its \_\_\_\_ DV using B-F equation:

$$D_x(y) \leftarrow \min_{v} \{c(x,v) + D_v(y)\}$$
 for each node  $y \in N$ 

\* under minor, natural conditions, the estimate  $D_x(y)$  converge to the actual least cost  $d_x(y)$ 

# iterative, asynchronous: each local iteration

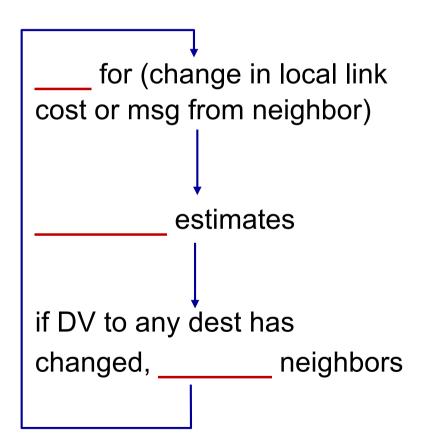

caused by:

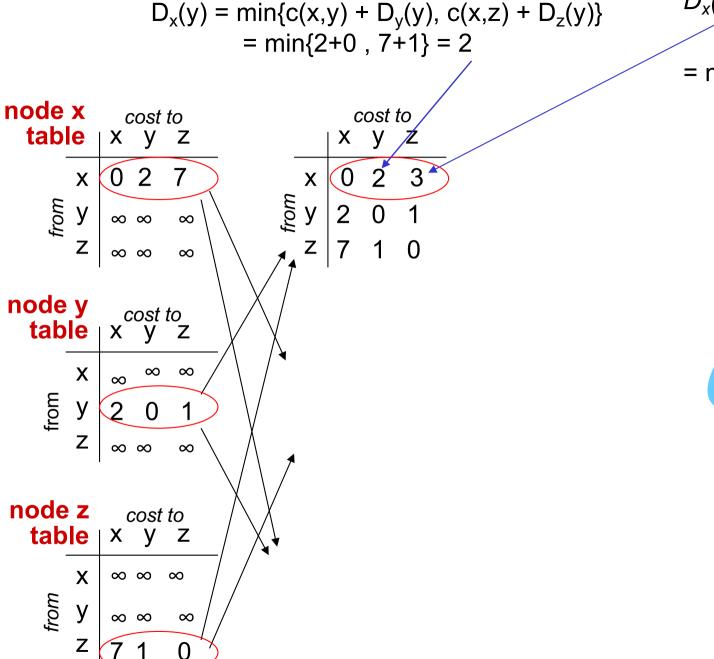

- local link cost change
- DV update message from neighbor

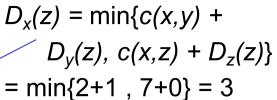

#### distributed:

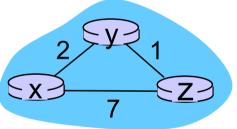

- each node notifies neighbors only when its DV changes
  - neighbors then notify their neighbors if necessary

#### each node:

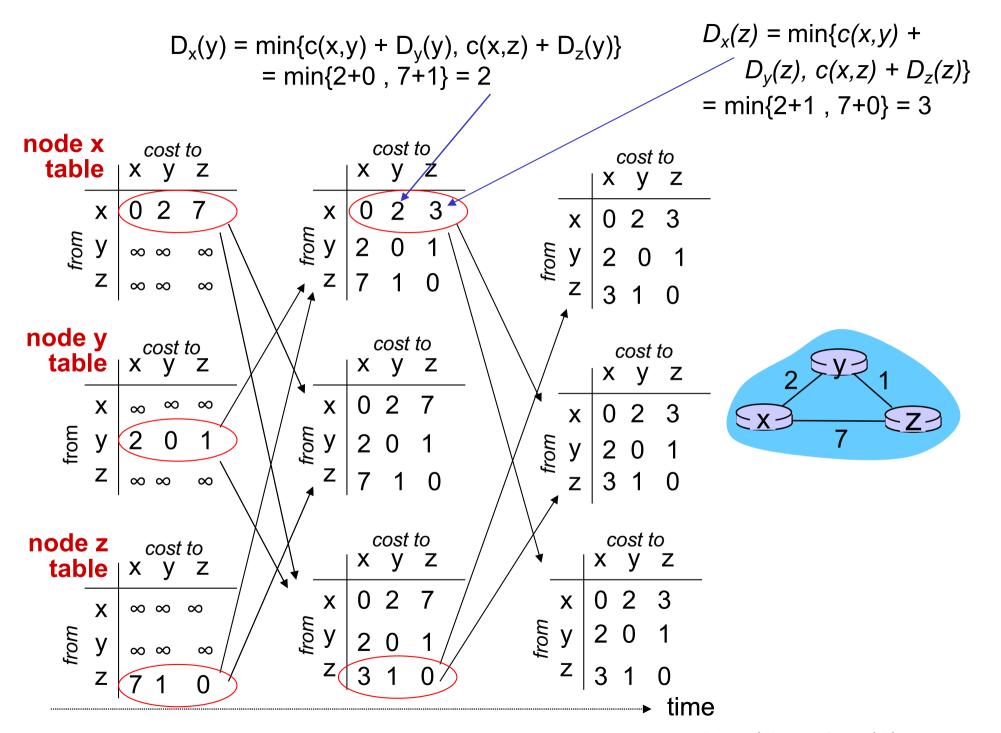

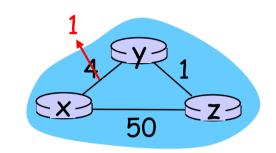

time

#### Distance vector: link cost changes

#### link cost changes:

- node detects local link cost change
- updates routing info, recalculates distance vector
- if DV changes, notify neighbors

"good news travels fast"  $t_0$ : y detects link-cost change, updates its DV, informs its neighbors.

 $t_1$ : z receives update from y, updates its table, computes new least cost to x, sends its neighbors its DV.

 $t_2$ : y receives z's update, updates its distance table. y's least costs do not change, so y does not send a message to z.

<sup>\*</sup> Check out the online interactive exercises for more examples: http://gaia.cs.umass.edu/kurose\_ross/interactive/

#### Distance vector: link cost changes

#### link cost changes:

- node detects local link cost change
- bad news travels slow "count to infinity" problem!
- 44 iterations before algorithm stabilizes: see text

#### poisoned reverse:

- If Z routes through Y to get to X:
  - Z tells Y its (Z's) distance to X is infinite (so Y won't route to X via Z)
- will this completely solve count to infinity problem?

#### Comparison of LS and DV algorithms

#### message \_\_\_\_\_

- LS: with n nodes, E links, O(nE) msgs sent
- DV: exchange between neighbors only
  - convergence time varies

#### speed of \_

- LS: O(n²) algorithm requires
   O(nE) msgs
  - may have oscillations
- DV: convergence time varies
  - may be routing loops
  - count-to-infinity problem

: what happens if router malfunctions?

#### LS:

- node can advertise incorrect link cost
- each node computes only its own table

#### DV:

- DV node can advertise incorrect path cost
- each node's table used by others
  - error propagate thru network

# Chapter 5: outline

- 5.1 introduction
- 5.2 routing protocols
- link state
- distance vector
- 5.3 intra-AS routing in the Internet: OSPF
- 5.4 routing among the ISPs: BGP

- 5.6 ICMP: The Internet Control Message Protocol
- 5.7 Network management and SNMP

### Making routing scalable

our routing study thus far - idealized

- all routers identical
- network "flat"
- ... not true in practice

# scale: with billions of destinations:

- can't store all destinations in routing tables!
- routing table exchange would swamp links!

#### administrative autonomy

- internet = network of networks
- each network admin may want to control routing in its own network

## Internet approach to scalable routing

aggregate routers into regions known as "\_\_\_\_\_\_" (AS) (a.k.a. "\_\_\_\_\_\_")

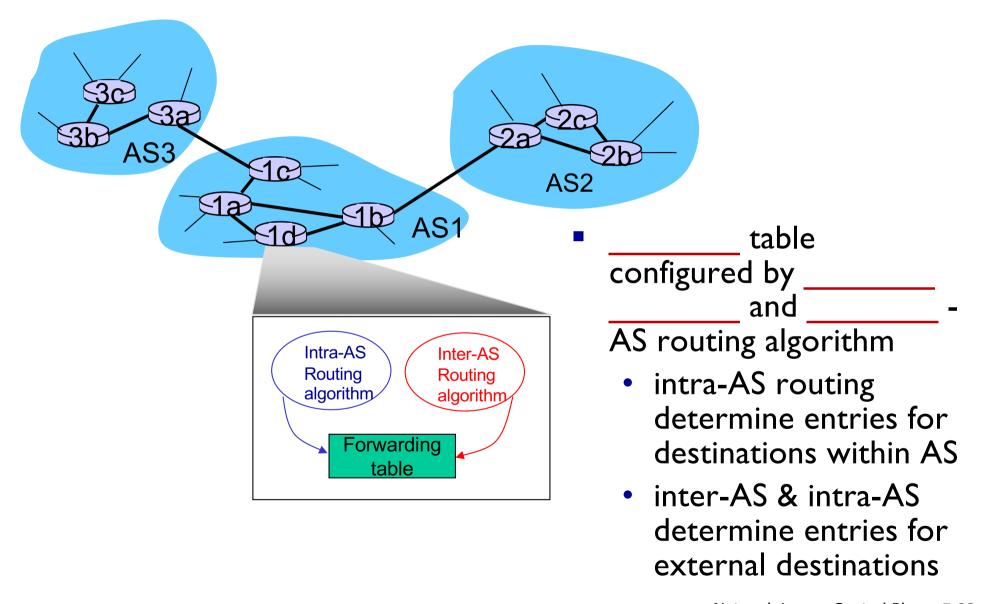

#### -AS routing

- routing among hosts, routers in \_\_\_\_\_ AS ("network")
- all routers in AS must run same intra-domain protocol
- routers in different AS can run different intra-domain routing protocol
- gateway router: at "\_\_\_\_' of its own AS, has link(s) to router(s) in other AS'es

#### \_-AS routing

- routing \_\_\_\_\_ AS'es
- gateways perform interdomain routing (as well as intra-domain routing)

### Interconnected ASes

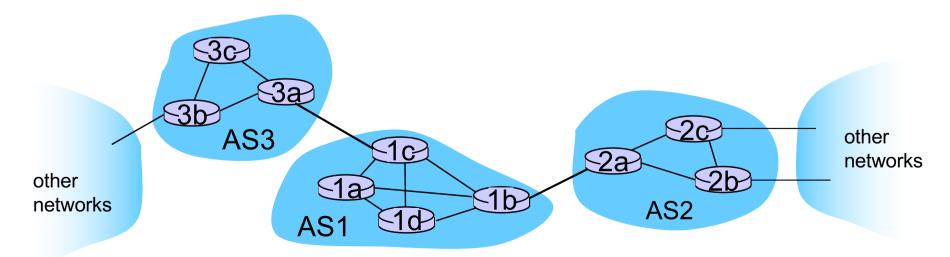

### Inter-AS tasks

- suppose router in AS1 receives datagram destined outside of AS1:
  - router should forward packet to gateway router, but which one?

#### AS1 must:

- learn which \_\_\_\_\_ are through AS2, which through AS3
- 2. \_\_\_\_ this \_\_\_\_ info to all routers in AS1

job of inter-AS routing!

### Intra-AS Routing

- also known as \_\_\_\_\_ protocols (IGP)
- most common intra-AS routing protocols:
  - RIP: Routing Information Protocol
  - OSPF: Open Shortest Path First (IS-IS protocol essentially same as OSPF)
  - IGRP: Interior Gateway Routing Protocol (Cisco proprietary for decades, until 2016)

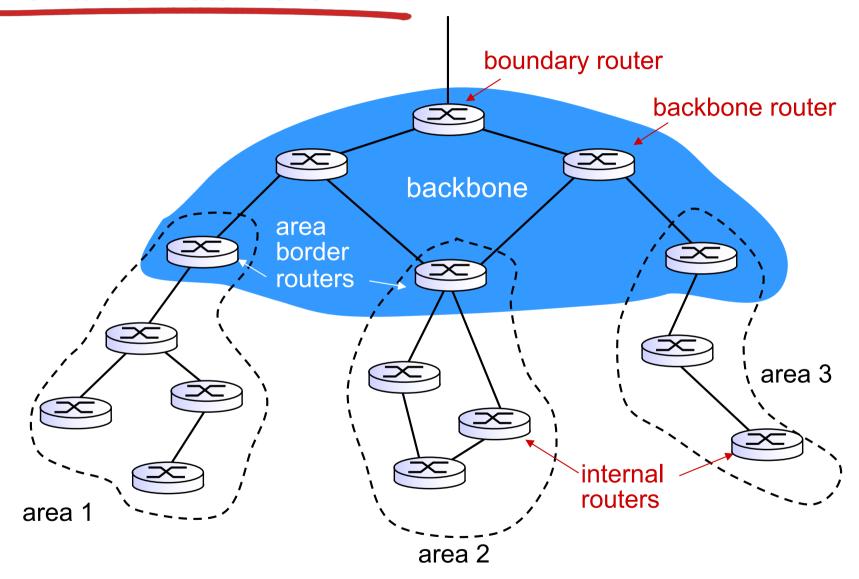

### OSPF (Open Shortest Path First)

- "open": publicly available
- uses link-state algorithm
  - link state packet \_\_\_\_\_
  - topology map at each node
  - route computation using Dijkstra's algorithm
- router \_\_\_\_\_ OSPF link-state \_\_\_\_\_ to all other routers in entire AS
  - carried in OSPF messages directly over IP (rather than TCP or UDP
  - link state: for each attached link
- IS-IS routing protocol: nearly identical to OSPF

### OSPF "advanced" features

- security: all OSPF messages \_\_\_\_\_\_ (to prevent malicious intrusion)
- multiple same-cost paths allowed (only one path in RIP)
- for each link, multiple cost metrics for different TOS (e.g., satellite link cost set low for best effort ToS; high for real-time ToS)
- integrated uni- and multi-cast support:
  - Multicast OSPF (MOSPF) uses same topology data base as OSPF
- hierarchical OSPF in large domains.

### Hierarchical OSPF

# Hierarchical OSPF

- two-level hierarchy: local area, backbone.
  - link-state advertisements only in area
  - each nodes has detailed area topology; only know direction (shortest path) to nets in other areas.
- area border routers: "summarize" distances to nets in own area, advertise to other Area Border routers.
- backbone routers: run OSPF routing limited to backbone.
- boundary routers: connect to other AS' es.

# Chapter 5: outline

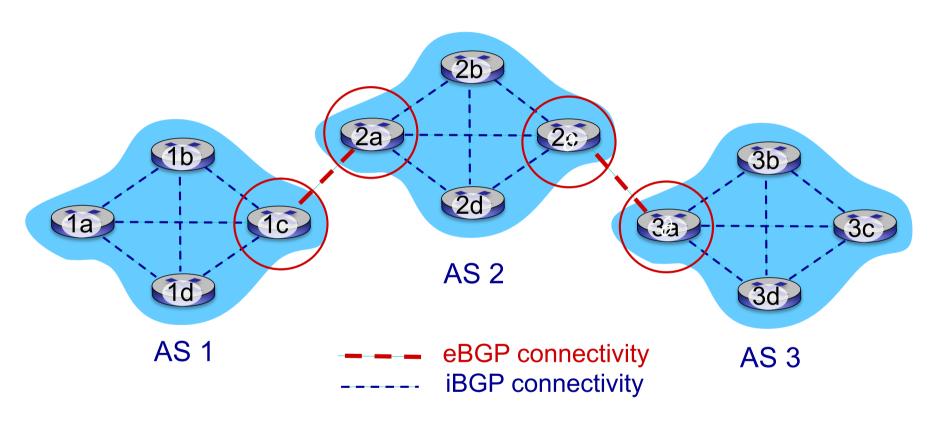

- 5.1 introduction
- 5.2 routing protocols
- link state
- distance vector
- 5.3 intra-AS routing in the Internet: OSPF
- 5.4 routing among the ISPs: BGP

- 5.6 ICMP: The Internet Control Message Protocol
- 5.7 Network management and SNMP

### Internet inter-AS routing: BGP

- BGP (\_\_\_\_\_\_\_): the de facto inter-domain routing protocol
  - "glue that holds the Internet together"
- BGP provides each AS a means to:
  - subnet \_\_\_\_\_ information from neighboring ASes
  - \_\_\_\_\_ information to all AS-internal routers.
  - determine "good" routes to other networks based on reachability information and policy
- allows subnet to advertise its existence to rest of Internet: "1 am here"

## eBGP, iBGP connections

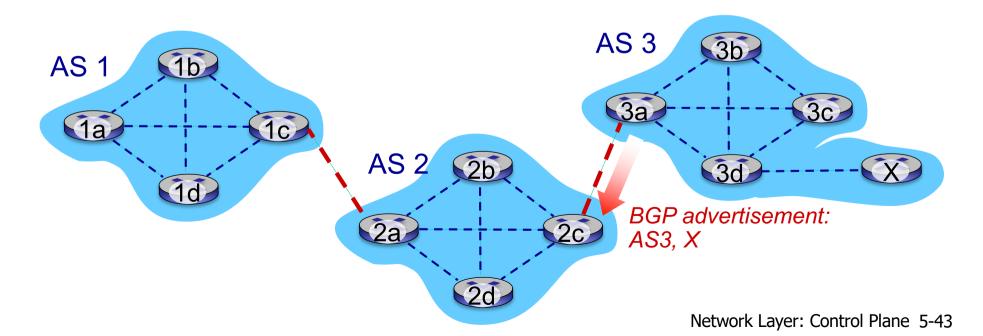

gateway routers run both eBGP and iBGP protocols

## **BGP** basics

- BGP session: two BGP routers ("peers") exchange BGP messages over semi-permanent TCP connection:
  - advertising paths to different destination network prefixes (BGP is a "path vector" protocol)
- when AS3 gateway router 3a advertises path AS3,X to AS2 gateway router 2c:
  - AS3 promises to AS2 it will forward datagrams towards X

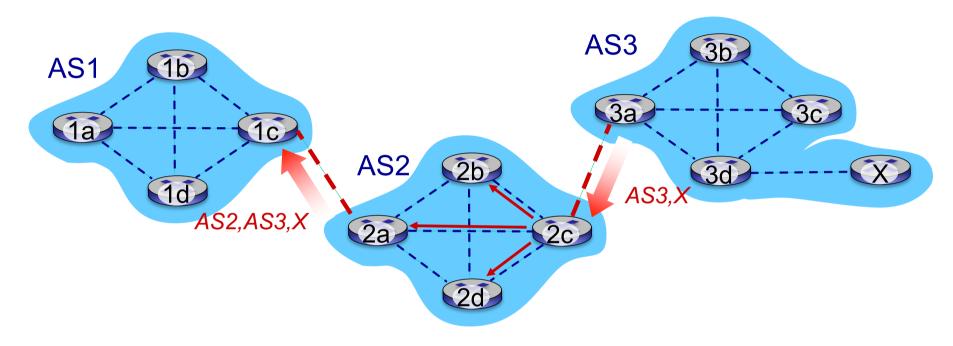

### Path attributes and BGP routes

- advertised prefix includes BGP attributes
  - prefix + attributes = "route"
- two important attributes:
  - \_\_\_\_\_: list of ASes through which prefix advertisement has passed
  - indicates specific internal-AS router to nexthop AS
- Policy-based routing:

  - AS policy also determines whether to advertise path to other other neighboring ASes

# BGP path advertisement

- AS2 router 2c receives path advertisement AS3,X (via eBGP) from AS3 router 3a
- Based on AS2 policy, AS2 router 2c accepts path AS3,X, propagates (via iBGP) to all AS2 routers
- Based on AS2 policy, AS2 router 2a advertises (via eBGP) path AS2, AS3, X to AS1 router 1c

# BGP path advertisement

gateway router may learn about multiple paths to destination:

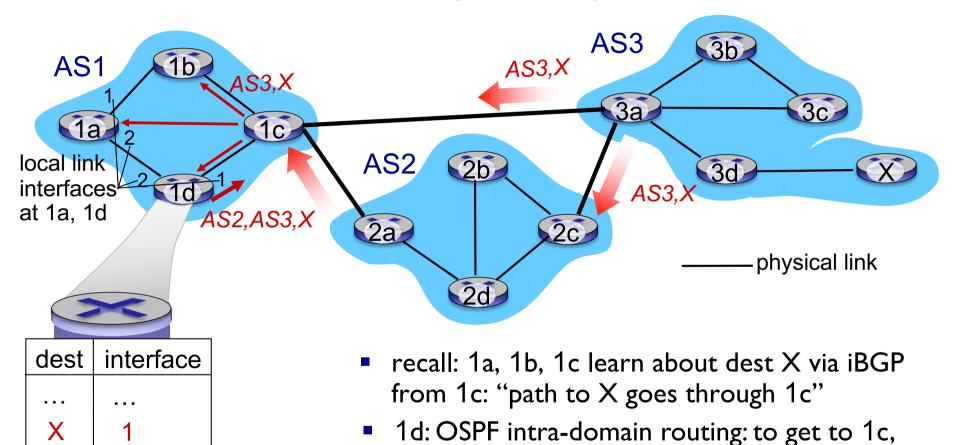

- AS1 gateway router 1c learns path AS2,AS3,X from 2a
- AS1 gateway router 1c learns path AS3,X from 3a
- Based on policy, AS1 gateway router 1c chooses path AS3, X, and advertises path within AS1 via iBGP

# BGP messages

- BGP messages exchanged between peers over TCP connection
- BGP messages:
  - OPEN: opens TCP connection to remote BGP peer and authenticates sending BGP peer
  - UPDATE: advertises new path (or withdraws old)
  - KEEPALIVE: keeps connection alive in absence of UPDATES; also ACKs OPEN request
  - NOTIFICATION: reports errors in previous msg; also used to close connection

### BGP, OSPF, forwarding table entries

Q: how does router set forwarding table entry to distant prefix?

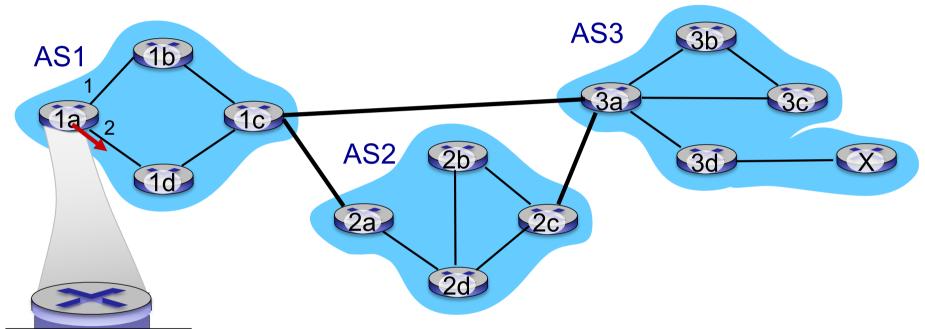

forward over outgoing local interface 1

Network Layer: Control Plane 5-48

### BGP, OSPF, forwarding table entries

Q: how does router set forwarding table entry to distant prefix?

dest	interface
X	2

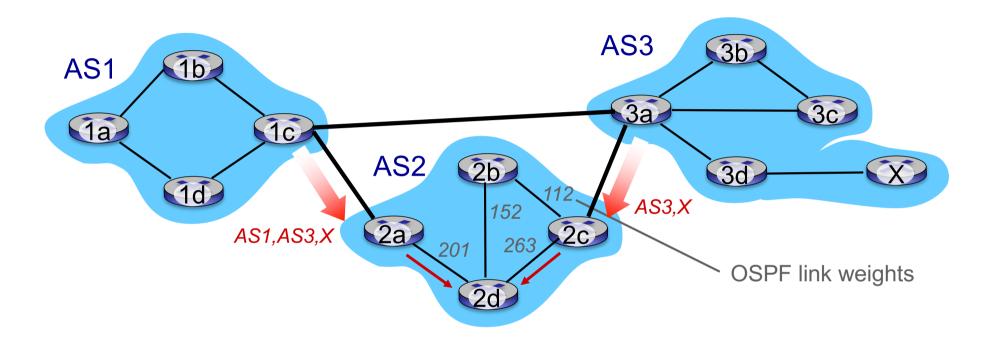

- recall: Ia, Ib, Ic learn about dest X via iBGP from Ic: "path to X goes through Ic"
- 1d: OSPF intra-domain routing: to get to 1c, forward over outgoing local interface 1
- 1a: OSPF intra-domain routing: to get to 1c, forward over outgoing local interface 2

### **BGP** route selection

- router may learn about more than one route to destination AS, selects route based on:
  - I. local preference value attribute: policy decision
  - 2. shortest AS-PATH
  - 3. closest NEXT-HOP router: hot potato routing
  - 4. additional criteria

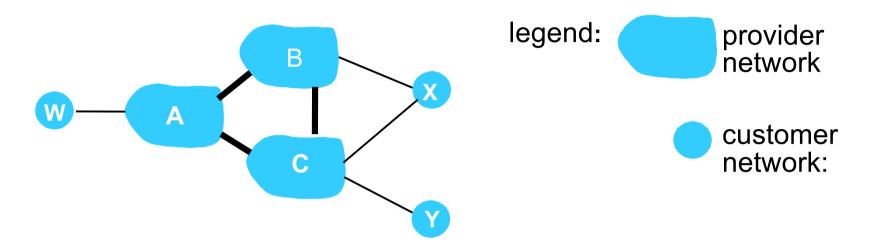

Network Layer: Control Plane 5-50

# Hot Potato Routing

- 2d learns (via iBGP) it can route to X via 2a or 2c
- hot potato routing: choose local gateway that has \_\_\_\_\_ intra-domain \_\_\_\_\_ (e.g., 2d chooses 2a, even though more AS hops to X): don't worry about inter-domain cost!

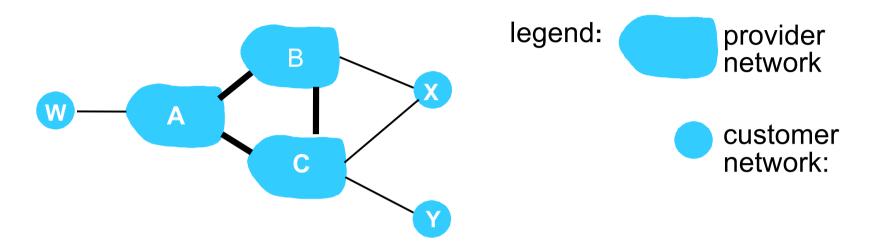

### BGP: achieving policy via advertisements

Suppose an ISP only wants to route traffic to/from its customer networks (does not want to carry transit traffic between other ISPs)

- A advertises path Aw to B and to C
- B chooses not to advertise BAw to C:
  - B gets no "revenue" for routing CBAw, since none of C,A, w are B's customers
  - C does not learn about CBAw path
- C will route CAw (not using B) to get to w

### BGP: achieving policy via advertisements

Suppose an ISP only wants to route traffic to/from its customer networks (does not want to carry transit traffic between other ISPs)

- A,B,C are provider networks
- X,W,Y are customer (of provider networks)
- X is dual-homed: attached to two networks
- policy to enforce: X does not want to route from B to C via X
  - .. so X will not advertise to B a route to C

### Why different Intra-, Inter-AS routing?

#### policy:

- inter-AS: admin wants \_\_\_\_\_ over how its traffic routed, who routes through its net.
- intra-AS: single admin, so no policy decisions needed scale:
- routing \_\_\_\_\_ size, reduced update traffic

#### performance:

- intra-AS: can focus on performance
- inter-AS: policy may dominate over performance

# Chapter 5: outline

- 5.1 introduction
- 5.2 routing protocols
- link state
- distance vector
- 5.3 intra-AS routing in the Internet: OSPF
- 5.4 routing among the ISPs: BGP

- 5.6 ICMP: The Internet Control Message Protocol
- 5.7 Network management and SNMP

### ICMP:

	used by hosts & routers					
	•	vork-	<u>Type</u>	<u>Code</u>	<u>description</u>	
	level information	VOTIK	0	0	echo reply (ping)	
	ievei iiiioi iiiauoii		3	0	dest. network unreachable	
	• reporting:		3	1	dest host unreachable	
	unreachable host, no	etwork,	3	2	dest protocol unreachable	
	port, protocol		3	3	dest port unreachable	
	• request/re	eply	3	6	dest network unknown	
	(used by ping)		3	7	dest host unknown	
	network-layer "abo	ve" IP:	4	0	source quench (congestion	
	<ul> <li>ICMP msgs carried i</li> </ul>				control - not used)	
	datagrams		8	0	echo request (ping)	
	ICMP message: type, code	9	0	route advertisement		
		10	0	router discovery		
	plus first 8 bytes of IP		11	0	TTL expired	
	datagram causing er	ror	12	0	bad IP header	

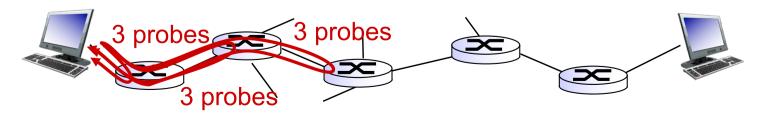

### Traceroute and ICMP

- source sends series of UDP segments to destination
  - first set has TTL = I
  - second set has TTL=2, etc.
  - unlikely port number
- when datagram in nth set arrives to nth router:
  - router discards datagram and sends source ICMP message (type II, code 0)
  - ICMP message include name of router & IP address

 when ICMP message arrives, source records RTTs

#### stopping criteria:

- UDP segment eventually arrives at destination host
- destination returns ICMP "port unreachable" message (type 3, code 3)
- source stops

# Chapter 5: outline

- 5.1 introduction
- 5.2 routing protocols
- link state
- distance vector
- 5.3 intra-AS routing in the Internet: OSPF
- 5.4 routing among the ISPs: BGP

- 5.6 ICMP: The Internet Control Message Protocol
- 5.7 Network management and SNMP

# What is network management?

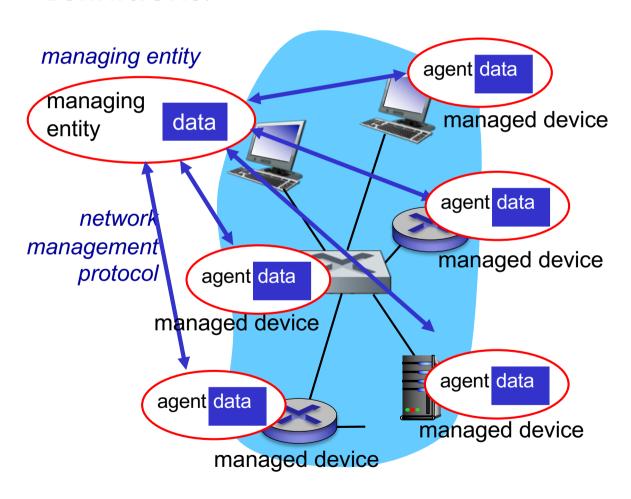

- autonomous systems (aka "network"): 1000s of interacting hardware/software components
- other complex systems requiring monitoring, control:
  - jet airplane
  - nuclear power plant
  - others?

"Network mana	igement includ	les the		
and	_ of the	,	, and human	
elements to monitor, test, poll, configure, analyze, evaluate,				
and control the network and element resources to meet the				
, opera		, and	of	
requirements a	t a			

### Infrastructure for network management

#### definitions:

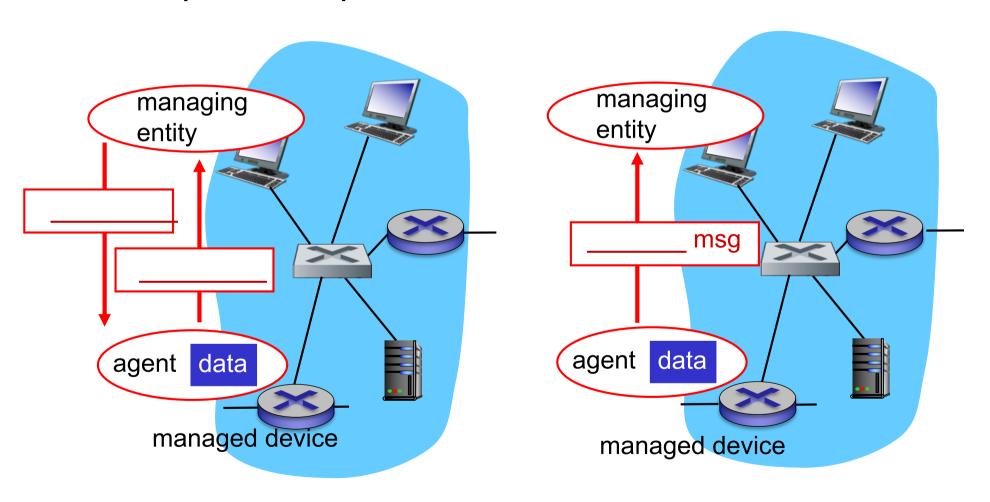

managed devices
contain managed
objects whose data is
gathered into a

(MIB)

# SNMP protocol

Two ways to convey MIB info, commands:

request/response mode

trap mode

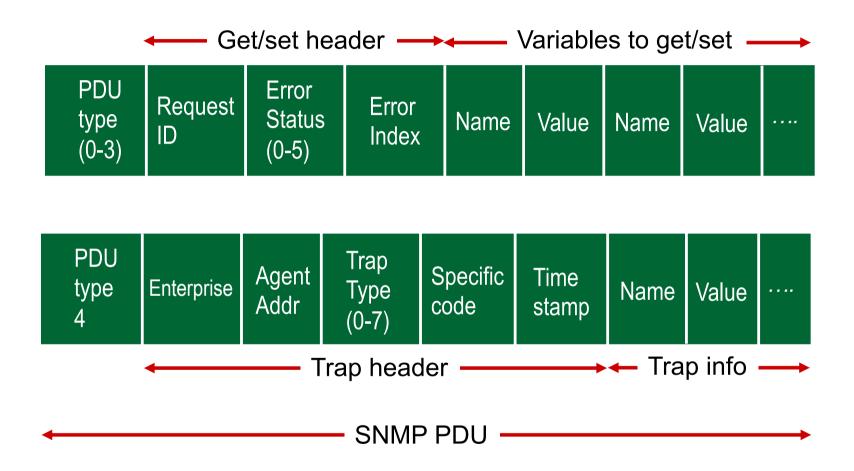

Network Layer: Control Plane 5-61

# SNMP protocol: message types

Message type	<u>Function</u>
GetRequest GetNextRequest GetBulkRequest	manager-to-agent: "get me data" (data instance, next data in list, block of data)
InformRequest	manager-to-manager: here's MIB value
SetRequest	manager-to-agent: set MIB value
Response	Agent-to-manager: value, response to Request
Trap	Agent-to-manager: inform manager of exceptional event

Network Layer: Control Plane 5-62

# SNMP protocol: message formats

More on network management: see earlier editions of text!

## Chapter 5: summary

#### we've learned a lot!

- approaches to network control plane
  - per-router control (traditional)
  - logically centralized control (software defined networking)
- traditional routing algorithms
  - implementation in Internet: OSPF, BGP
- Internet Control Message Protocol
- network management

next stop: link layer!
